

1 **ABSTRACT**

2 Described herein is audio watermarking technology for inserting and
3 detecting watermarks in audio signals, such as a music clip. The watermark
4 identifies the content producer, providing a signature that is embedded in the audio
5 signal and cannot be removed. The watermark is designed to survive all typical
6 kinds of processing and malicious attacks. In one described implementation, a
7 watermarking system employs covert channel encoder to layer an additional
8 information data message on top of the watermark. Thus, an informational
9 message is imposed upon the existing watermark encoded in a signal. In another
10 described implementation, a watermarking system employs a permutation
11 technique to further hide the watermark and it may hide the covert message within
12 the watermark. The order in which data is imposed or encoded is rearranged
13 based upon a permutation table. The same table is used to reverse permute the
14 data at the detector.
